ON NONPLANAR GRAPHS WITH THE MINIMUM NUMBER OF VERTICES
 AND A GIVEN GIRTH

Milan KOMAN, Praha

By the girth of a graph G we mean according to H.-J. Voss [2] the length of the shortest circuit included in the graph G . According to the well known theorem of G. Kuratowski [1] an arbitrary graph is nonplanar if and only if it includes a subgraph which is homeomorphic with the complete graph K_5 (Fig.1) or the regular bicomplete graph $K_{3,3}$ (Fig. 2).

Fig. 1

Fig. 2

Fig. 3

For example the so called Petersen graph P (Fig.3)

which is not a planar graph contains a subgraph homeomorphic with the graph $K_{3,3}$ (in Fig.3 the edges of this subgraph are denoted by thick lines).

The graph K_5 is a nonplanar graph with a girth $t(K_5) = 3$; the graph $K_{3,3}$ is a nonplanar graph with a girth $t(K_{3,3}) = 4$. Petersen's graph P is a nonplanar graph with a girth $t(P) = 5$.

Now the natural question arises: Which is the minimum number v_n ($n \geq 4$) of vertices of nonplanar graphs

G which have a girth $t(G) = n$.

The answer is given in

Theorem 1. The minimum number v_n ($n \geq 4$) of vertices of all nonplanar graphs G which have a girth $t(G) = n$ is equal to

$$v_n = \left[\frac{9(n-1)}{4} \right] + d_n, \quad (n \geq 4)$$

where

$$d_n = 0 \quad \text{if } n \not\equiv 3 \pmod{4};$$

$$d_n = 1 \quad \text{if } n \equiv 3 \pmod{4}.$$

Proof: a) First we shall show that

$$v_n \leq u_n = \left[\frac{9(n-1)}{4} \right] + d_n.$$

Therefore we shall construct a nonplanar graph G_n of the given girth n which has exactly u_n vertices. The number u_n can be expressed in the form

$$w_m = 6 + 9 \left[\frac{m-4}{4} \right] + \kappa_m$$

where

$$\kappa_m = 0 \quad \text{if} \quad m \equiv 0 \pmod{4};$$

$$\kappa_m = 3 \quad \text{if} \quad m \equiv 1 \pmod{4};$$

$$\kappa_m = 5 \quad \text{if} \quad m \equiv 2 \pmod{4};$$

$$\kappa_m = 8 \quad \text{if} \quad m \equiv 3 \pmod{4}.$$

Now let us construct the graph $K_{3,3}$ (Fig.2). On each of the edges h_i , where $i = 1, 2, \dots, \kappa_m$ we choose $\left[\frac{m}{4} \right]$ new vertices. On each of the remaining edges h_j ($j = \kappa_m + 1, \kappa_m + 2, \dots, 9$) let us choose $\left[\frac{m-4}{4} \right]$ new vertices. In this way we obtain the graph G_m which has w_m vertices. The graph $K_{3,3}$ contains only quadrangles and hexagons. The quadrangles of the graph $K_{3,3}$ turn into polygons with at least m vertices in the graph G_m (see Table 1). From the hexagons of graph $K_{3,3}$ circuits of a shorter length than $6 \left[\frac{m}{4} \right]$ cannot develop in graph G_m . Which is always at least m for $m \neq 7, m \geq 4$. If $m = 7$, then every circuit of the graph G_m which develops from the hexagon of graph $K_{3,3}$ has the length of at least 11. Besides the circuits which have developed from quadrangles and hexagons in the graph $K_{3,3}$ there are no other circuits in the graph G_m .

So the inequality $v_n \leq w_n$ is proved.

b) We shall prove the equation $w_n = v_n$. We can apparently suppose that the nonplanar graph G_n^* with a girth n which has the minimum number of vertices: v_n is itself homeomorphic with the graph K_5 or $K_{3,3}$.

Table of lengths of circuits in the graph G_n which are induced by the quadrangles of the graph $K_{3,3}$.				
Quadrangles induced by edges	$n \equiv 0 \pmod{4}$	$n \equiv 1 \pmod{4}$	$n \equiv 2 \pmod{4}$	$n \equiv 3 \pmod{4}$
$h_1 h_4 h_2 h_6$	n	$n + 1$	n	$n + 1$
$h_2 h_9 h_3 h_8$	n	$n + 1$	n	n
$h_1 h_4 h_8 h_6$	n	n	n	$n + 1$
$h_3 h_4 h_4 h_9$	n	n	n	n
$h_1 h_4 h_9 h_5$	n	n	n	n
$h_1 h_8 h_6 h_5$	n	n	n	$n + 1$
$h_1 h_4 h_3 h_5$	n	$n + 1$	$n + 2$	$n + 1$
$h_2 h_4 h_4 h_8$	n	n	n	$n + 1$
$h_2 h_6 h_5 h_9$	n	n	n	n

Table 1

Let us first suppose that the graph G_n^* is homeomorphic with the graph K_5 . Therefore we can construct the graph G_n^* from the graph K_5 so that we choose $v_n - 5$ new vertices on its edges. Then on every triangle of the graph K_5 we must choose at least $n - 3$ new vertices. In the graph K_5 there are, on the whole, 10 different triangles, while every edge be-

longs to three triangles. So the graph G_m^* develops from the graph K_5 by adding at least

$$\left[\frac{10(m-3)+2}{3} \right]$$

vertices. Therefore

$$\left[\frac{10(m-3)+2}{3} \right] \leq v_m - 5 \leq w_m - 5 = 1 + 9 \left[\frac{m-4}{4} \right] + n_m.$$

Because the inequality

$$\left[\frac{10(m-3)+2}{3} \right] \leq 1 + 9 \left[\frac{m-4}{4} \right] + n_m$$

has no solution for $m \geq 4$, it is therefore proved that the graph G_m^* cannot be homeomorphic with the graph K_5 .

So the graph G_m^* is homeomorphic with the graph $K_{3,3}$. In other words it develops from the graph $K_{3,3}$, so that we choose $v_m - 6$ new vertices suitably on its edges. Simultaneously we must choose at least $m - 4$ new vertices on each quadrangle of the graph $K_{3,3}$. In the graph $K_{3,3}$ there are, on the whole, 9 different quadrangles, while each edge belongs to four quadrangles. The graph G_m^* therefore develops from the graph $K_{3,3}$ by adding at least

$$\left[\frac{9(m-4)+3}{4} \right]$$

vertices. Therefore

$$\left[\frac{9(m-4)+3}{4} \right] \leq v_m - 6 \leq w_m - 6 = 9 \left[\frac{m-4}{4} \right] + n_m$$

holds. It is easy to find out that

$$9 \left[\frac{n-4}{4} \right] + n_n - \left[\frac{9(n-4)+3}{4} \right] = d_n .$$

Hence for $n \not\equiv 3 \pmod{4}$ it follows that $v_n = w_n$ and for $n \equiv 3 \pmod{4}$ it follows that either $v_n = w_n$ or $v_n = w_n - 1$. We shall show that $v_n \neq w_n - 1$ holds even for $n \equiv 3 \pmod{4}$. Let us, on the contrary, suppose that $v_n = w_n - 1$. The edges of the graph $K_{3,3}$ which contains less than $\left[\frac{n}{4} \right]$ new vertices (i.e. vertices which must be added to the edges of graph $K_{3,3}$ for it to become graph G_n^*), induces in $K_{3,3}$ a subgraph Q which has at least two edges and does not contain a quadrangle. For should the graph Q contain a quadrangle F , then in the graph G_n^* there would exist a circuit of the length $n - 3$, and that is a contradiction. It is easy to find out that the subgraph Q must be isomorphic with some subgraph which is induced by these sets of edges of the graph $K_{3,3}$ (see Fig.2):

$$\begin{array}{ll} E_1 = \{h_1, h_2\}, & E_5 = \{h_1, h_2, h_3\}, \\ E_2 = \{h_1, h_6\}, & E_6 = \{h_1, h_2, h_3\}, \\ E_3 = \{h_1, h_6, h_7\}, & E_7 = \{h_1, h_6, h_7, h_8\}, \\ E_4 = \{h_1, h_4, h_7\}, & E_8 = \{h_1, h_4, h_6, h_7\}, \end{array}$$

$$\begin{aligned}
E_9 &= \{h_1, h_2, h_6, h_7\}, & E_{12} &= \{h_1, h_4, h_6, h_7, h_9\}, \\
E_{10} &= \{h_1, h_3, h_6, h_7\}, & E_{13} &= \{h_1, h_4, h_5, h_6, h_7\}, \\
E_{11} &= \{h_1, h_3, h_6, h_7, h_9\}, & E_{14} &= \{h_1, h_3, h_6, h_7, h_8, h_9\}.
\end{aligned}$$

Let us denote by x_i ($i = 1, 2, \dots, 9$) the number of new vertices which we must choose on the edge h_i of the graph $K_{3,3}$ if we want to obtain the graph G_m^* . Let us further denote

$$\begin{aligned}
x_i &= x_i - \left[\frac{n-4}{4} \right], \quad \text{if } x_i \notin Q, \\
y_i &= x_i - \frac{n-4}{4}, \quad \text{if } x_i \in Q.
\end{aligned}$$

Obviously for all permissible i

$$(N) \quad x_i > 0, \quad y_i \leq 0$$

holds. Further

$$(R) \quad \sum_{x_i \notin Q} x_i + \sum_{x_i \in Q} y_i = \gamma$$

holds. Because on the edge of every quadrangle F of the graph $K_{3,3}$ there are at least $n-4$ new vertices, the inequality

$$(F) \quad \sum_{\substack{x_i \notin Q \\ x_i \in F}} x_i + \sum_{\substack{x_i \in Q \\ x_i \in F}} y_i \geq 3.$$

also holds. If the quadrangle F is induced by the edges h_u, h_v, h_t, h_w then we shall further denote the inequality (F) shortly by $(\kappa v t u)$.

Now we shall show that all 14 possibilities for the

graph Q lead to a contradiction.

1) Let the graph Q be induced by one of the sets of edges $E_1, E_2, E_3, E_4, E_5, E_7, E_8$. Then from the inequality (R), inequalities (N) and inequalities (1267), (1468), (2478) we obtain contradictory inequalities

$$6 \leq 2x_3 + 2x_5 + 2x_8 \leq 5.$$

2) Let the graph Q be induced by the set of edges E_6 . Then from the equality (R), inequalities (N) and inequalities (1267), (1345), (2389) we get the contradictory inequalities

$$6 \leq x_4 + x_5 + x_6 + x_7 + x_8 + x_9 \leq 5.$$

3) Let the graph Q be induced by one of the sets $E_9, E_{11}, E_{12}, E_{13}, E_{14}$. Then from the equality (R), inequalities (N) and inequalities (1468), (1579), (3479), (3568) we get

$$2 \leq 2x_2 \leq 2$$

or $x_2 = 1$. Simultaneously the inequality (1267) must hold, i.e. the inequality

$$y_1 + x_2 + y_6 + y_7 \geq 3.$$

It is, however, with respect to the equality $x_2 = 1$, in contradiction with the inequalities (N).

4) Finally let the graph Q be induced by the set of edges E_{10} . Then from the equality (R), inequalities (N) and inequalities (1267), (1468), (1579), (2389), (3479), (3569) we get

$$3 \leq x_2 + x_4 + x_5 \leq 3$$

so that $x_2 = x_4 = x_5 = 1$. Simultaneously the inequality (1345) must hold, i.e. the inequality

$$y_1 + y_3 + x_4 + x_5 \geq 3.$$

But that is, with regard to the equalities $x_4 = x_5 = 1$, in contradiction to the inequalities (N).

So the possibility $v_m = w_m - 1$ is excluded even for the case $m \equiv 3 \pmod{4}$. So the whole theorem is proved.

From Theorem 1 the following simple result follows:

Result. If G is an arbitrary graph which has less than v_m vertices and has a girth m , then this graph is a planar one.
