TOLERANCE RELATIONS ON COMPLETE LATTICES

Juhani NIEMINEN, Vaasa

Abstract: It is shown that each compatible tolerance relation  $T$  on a complete lattice  $L$  has a homotopy representation by means of two semicongruences induced by  $T$  on  $L$ .

Key words: Tolerance, homotopy representation.

AMS: 06A23

Ref. Ž.: 2.724.38

-----

The purpose of this short paper is to show that each compatible tolerance relation on a complete lattice has the property of the homotopy type, i.e. a compatible tolerance relation  $T$  on a complete lattice  $L$  can be decomposed into two semicongruences on  $L$  and, on the other hand, expressed by means of these two semicongruences. The concept of homotopy suitable for the approach here was introduced by Petrescu in [4]. The other observations of this note are based on the characterization of compatible tolerance relations by means of  $\sim$ -coverings and related mappings given by Chajda, Niederle and Zelinka in [1]. For other properties of tolerance relations on algebras the reader is referred to the recent paper [3] of Chajda and Zelinka and to the references therein.

Let  $\mathcal{A} = \langle A, F \rangle$  be an algebra with the support  $A$  and

the set  $F$  of fundamental operations. A tolerance relation  $T$  on the set  $A$  is a binary, reflexive and symmetric relation on  $A$ .  $T$  is compatible with  $\mathcal{A}$ , if for any  $n$ -ary operation  $f \in F$ , where  $n$  is a positive integer, and for arbitrary elements  $a_1, \dots, a_n, b_1, \dots, b_n$  of satisfying  $a_i T b_i$  for  $i = 1, \dots, n$ , we have  $f(a_1, \dots, a_n) T f(b_1, \dots, b_n)$ .

Let  $M$  be a non-empty set. The family  $\mathcal{M} = \{M_\gamma, \gamma \in \Gamma\}$ , where  $\Gamma$  is a subscript set, is called a covering of  $M$  by subsets, if and only if  $M_\gamma$  is for each  $\gamma \in \Gamma$  a subset of  $M$  and  $\bigcup_{\gamma \in \Gamma} M_\gamma = M$ . As usually, we suppose that  $M_\gamma \neq M_\beta$  for  $\gamma \neq \beta, \gamma, \beta \in \Gamma$ . A covering  $\mathcal{M} = \{M_\gamma, \gamma \in \Gamma\}$  of  $M$  is called a  $\tau$ -covering of  $M$ , if and only if  $\mathcal{M}$  satisfies the following two conditions

- (i) if  $\gamma_0 \in \Gamma$  and  $\Gamma_0 \subseteq \Gamma$ , then  $M_{\gamma_0} \subseteq \bigcup_{\gamma \in \Gamma_0} M_\gamma$  and  $\bigcap_{\gamma \in \Gamma_0} M_\gamma \subseteq M_{\gamma_0}$ ;
- (ii) if  $N \subseteq M$  and  $N$  is not contained in any set from  $\mathcal{M}$ , then  $N$  contains a two-element subset of the same property.

The following lemma shows the connection between tolerance relations on  $M$  and  $\tau$ -coverings of  $M$  [1, Thm. 1].

**Lemma 1.** Let  $M$  be a non-empty set. There exists then a one-to-one correspondence between tolerance relations on  $M$  and  $\tau$ -coverings of  $M$  such that if  $T$  is a tolerance relation on  $M$  and  $\mathcal{M}_T$  is the  $\tau$ -covering of  $M$  corresponding to  $T$ , then any two elements of  $M$  are in the relation  $T$  if and only if there exists a set from  $\mathcal{M}_T$  which contains both of them.

The second lemma [1, Thm. 3] illuminates the properties of compatible tolerances on algebras.

Lemma 2. Let  $\mathcal{A} = \langle A, F \rangle$  be an algebra,  $T$  a tolerance on  $\mathcal{A}$  and  $\mathcal{M}_T$  a  $\tau$ -covering of  $A$  corresponding to  $T$ . The tolerance  $T$  is compatible with  $\mathcal{A}$ , if and only if there exists an algebra  $\mathcal{B} = \langle B, G \rangle$  with the following properties:

(i) there exists a one-to-one mapping  $\varphi : F \rightarrow G$  such that for any positive integer  $n$  and for each  $f \in F$  the operation  $\varphi f$  is  $n$ -ary if and only if  $f$  is  $n$ -ary;

(ii) there exists a one-to-one mapping  $\chi : \mathcal{M}_T \rightarrow B$  such that for each  $n$ -ary operation  $f \in F$  and for any  $n + 1$  elements  $M_0, M_1, \dots, M_n$  from  $\mathcal{M}_T$  the equality  $\varphi f(\chi(M_1), \dots, \chi(M_n)) = \chi(M_0)$  implies that for any  $n$  elements  $a_1, \dots, a_n$  of  $A$  such that  $a_i \in M_i$ ,  $i = 1, \dots, n$ , the element  $f(a_1, \dots, a_n) \in M_0$ .

Let  $\mathcal{A} = \langle A, F \rangle$  and  $\mathcal{B} = \langle B, G \rangle$  be two algebras of the same type. Let  $n_0$  be the maximum number  $n$  for which there exists an  $n$ -ary operation  $f$  on  $\mathcal{A}$  and  $I$  the interval  $[1, n_0]$ . A family  $\xi = [(\alpha_i)_{i \in I}; \beta]$  of mappings of  $A$  into  $B$  such that  $\beta(f(a_1, \dots, a_n)) = f(\alpha_1(a_1), \dots, \alpha_n(a_n))$  for every  $n \leq n_0$ ,  $a_1, \dots, a_n \in A$ , is called a homotopy of  $\mathcal{A}$  into  $\mathcal{B}$ . The mappings  $\alpha_i$  are called components of homotopy  $\xi$  and  $\beta$  the principal component of  $\xi$ . Moreover, it is shown that each  $\alpha_i$  induces an equivalence relation on  $A$  [4, Lemma 0.1].

We shall show that the mapping  $\chi$  relating to a compatible tolerance  $T$  on  $L$  is a principal component of a homotopy induced by  $T$ . The components  $\alpha_1$  and  $\alpha_2$  are generated by semicongruences on  $L$  which are induced by the  $\tau$ -covering  $\mathcal{M}_T$  of  $T$ . We shall construct  $\alpha_1$  which is given by an equivalence relation  $E(\alpha_1)$  being compatible with respect to the

$\wedge$ -operation on  $L$ , i.e. by a  $\wedge$ -semicongruence. The equivalence relation  $E(\alpha_1)$  is constructed by determining the partition  $\mathcal{E}$  inducing  $E(\alpha_1)$ .  $\mathcal{E}$  is obtained by modifying the  $\tau$ -covering  $\mathcal{M}_T$  of the compatible tolerance  $T$  on  $L$ .

**Theorem 1.** Let  $T$  be a compatible tolerance on a complete lattice  $L$ ,  $\mathcal{M}_T$  the  $\tau$ -covering corresponding to  $T$  and let  $M_\sigma \in \mathcal{M}_T$ . Then the family of sets  $\mathcal{M}_T^\wedge = \{M_\sigma^\wedge, \sigma \in \Gamma\}$ , where  $M_\sigma^\wedge = M_\sigma \setminus \bigcup_{\gamma \in \Gamma} \{M_\gamma \mid M_\gamma \cap M_\sigma \neq \emptyset\}$ , the least element  $e_{1\sigma}$  of  $M_\sigma$  is greater than the least element  $e_{1\gamma}$  of  $M_\gamma$  ( $e_{1\sigma} < e_{1\gamma}$ ),  $M_\gamma \in \mathcal{M}_T$ , forms a partition of  $L$  determining a  $\wedge$ -semicongruence on  $L$ .

**Proof.** According to [2, Thm. 1], each  $M_\gamma \in \mathcal{M}_T$  is a convex sublattice of  $L$ , and as  $L$  is complete, there are in  $M_\gamma$  the least and greatest elements  $e_{1\gamma}$  and  $e_{g\gamma}$ , respectively.

According to the definition of  $M_\sigma^\wedge$ , each  $M_\sigma^\wedge$  contains at least  $e_{1\sigma}$ , whence  $M_\sigma^\wedge \neq \emptyset$  for each  $\sigma \in \Gamma$ . Moreover, the properties of  $T$  imply that when  $a, b \in M_\sigma^\wedge$  then also  $a \wedge b \in M_\sigma^\wedge$ . Thus the theorem holds, if we can show that any element  $x \in L$  belongs to at least one set  $M_\sigma^\wedge$  of  $\mathcal{M}_T^\wedge$ , and  $M_\sigma^\wedge \cap M_\gamma^\wedge = \emptyset$  for each pair  $\sigma, \gamma \in \Gamma$  when  $\sigma \neq \gamma$ .

Let  $a \in L$  and  $\mathcal{M}_T(a)$  be the family of all subsets of  $\mathcal{M}_T$  containing the element  $a$ . Let  $M_\gamma, M_{\sigma\epsilon} \in \mathcal{M}_T(a)$  be such sets that  $e_{1\gamma}$  and  $e_{1\sigma\epsilon}$  are non-comparable. Let  $q$  be the least element of the set  $M_\gamma \cap M_{\sigma\epsilon}$ ; such an element  $q$  exists and  $q \in M_\gamma \cap M_{\sigma\epsilon}$ , since  $L$  is complete and as an intersection of two convex sets  $M_\gamma \cap M_{\sigma\epsilon}$  is a convex set of  $L$ , too. As  $q \in M_\gamma, M_{\sigma\epsilon}$ ,  $q \geq e_{1\gamma} \vee e_{1\sigma\epsilon}$  and as  $e_{1\gamma} \vee e_{1\sigma\epsilon} \in M_\gamma \cap M_{\sigma\epsilon}$ ,

$q \in e_{1\gamma} \vee e_{1\lambda}$ , whence  $q = e_{1\gamma} \vee e_{1\lambda}$ . According to the compatibility of  $T$ , any two elements of the interval  $[e_{1\gamma} \vee e_{1\lambda}, e_{g\gamma} \vee e_{g\lambda}]$  are in the relation  $T$ . Thus  $[e_{1\gamma} \vee e_{1\lambda}, e_{g\gamma} \vee e_{g\lambda}] \subseteq M_\lambda \in \mathcal{M}_T(a)$  for some index  $\lambda \in \Gamma$ . If  $e_{1\lambda} \leq e_{1\gamma}$ , then  $M_\gamma \notin \mathcal{M}_T$  according to the condition (i) for  $\mathcal{M}_T$ ; the same holds for  $M_\lambda$ , too. If  $e_{1\gamma}$  and  $e_{1\lambda}$  are non-comparable, then  $(e_{1\gamma} \wedge e_{1\lambda}) \in e_{g\gamma}$ , as  $e_{g\gamma} \in M_\gamma, M_\lambda$ . Then  $e_{1\gamma} > e_{1\gamma} \wedge e_{1\lambda}$ , and so there were in  $\mathcal{M}_T$  a set containing properly  $M_\gamma$ , which is a contradiction. Hence  $e_{1\gamma}, e_{1\lambda} \leq e_{1\lambda} \leq e_{1\gamma} \vee e_{1\lambda}$  and so  $e_{1\lambda} = e_{1\gamma} \vee e_{1\lambda}$ . Consequently, there is in  $\mathcal{M}_T(a)$  for any two sets  $M_\gamma, M_\lambda$  a third set  $M_\lambda$  such that  $e_{1\lambda} = e_{1\gamma} \vee e_{1\lambda}$ . As  $L$  is complete, there is also an element  $\bigvee_{\lambda \in \Gamma} e_{1\lambda}$  where  $\lambda$  goes over all indices of the sets in  $\mathcal{M}_T(a)$ ;  $e_{1\lambda}$  is the least element of a subset  $M_\lambda$  belonging to the  $\tau$ -covering  $\mathcal{M}_T$  and containing the element  $a$ . According to the definition of  $M_\lambda^\wedge$  and to the maximality of  $e_{1\lambda}$  with respect to  $a$ ,  $a \in M_\lambda^\wedge$ , and so any element of  $L$  belongs to at least one of the sets  $M_\lambda^\wedge, \lambda \in \Gamma$ .

If  $M_\lambda^\wedge \cap M_\mu^\wedge \neq \emptyset, \lambda \neq \mu$ , then we can prove as above that  $e_{1\lambda} \vee e_{1\mu} \in M_\lambda^\wedge \cap M_\mu^\wedge$ . But this is the least element of a subset  $M_\lambda \in \mathcal{M}_T, e_{1\lambda} > e_{1\lambda}, e_{1\mu}$ , and thus, according to the definitions of  $M_\lambda^\wedge$  and  $M_\mu^\wedge, e_{1\lambda} \in M_\lambda^\wedge, M_\mu^\wedge$ . This is a contradiction, whence  $M_\lambda^\wedge \cap M_\mu^\wedge = \emptyset$  for any pair  $\lambda, \mu \in \Gamma, \lambda \neq \mu$ . This completes the proof.

Let  $T$  be a compatible tolerance on a complete lattice  $L$  and  $\chi$  a mapping,  $\chi: \mathcal{M}_T \rightarrow B$ , induced by  $T$  and defined in Lemma 2. As for any  $\lambda \in \Gamma$  there exists a unique subset

$M_{\mathcal{T}}^{\wedge} \in \mathcal{M}_{\mathcal{T}}^{\wedge}$  of  $L$ , we can define a mapping  $\alpha_1: L \rightarrow B$  as follows: for any  $a \in L$ ,  $\alpha_1(a) = \chi(M_{\mathcal{T}}^{\wedge})$  if and only if  $a \in M_{\mathcal{T}}^{\wedge}$  in  $\mathcal{M}_{\mathcal{T}}^{\wedge}$ .

By using the dual proof of Theorem 1, we can show the existence of a partition  $\mathcal{M}_{\mathcal{T}}^{\vee}$  of  $L$  determining a  $\vee$ -semi-congruence on  $L$ . As above, we define the mapping  $\alpha_2: L \rightarrow B$  induced by  $\mathcal{M}_{\mathcal{T}}^{\vee}$  and  $\chi$ : for any  $a \in L$ ,  $\alpha_2(a) = \chi(M_{\mathcal{T}}^{\vee})$  if and only if  $a \in M_{\mathcal{T}}^{\vee}$  in  $\mathcal{M}_{\mathcal{T}}^{\vee}$ . Now we are able to state our main theorem

Theorem 2. Let  $L$  be a complete lattice,  $T$  a compatible tolerance on  $L$ ,  $\mathcal{M}_{\mathcal{T}}$  the corresponding  $\tau$ -covering of  $L$  and  $\chi$  the mapping,  $\chi: L \rightarrow B$ , induced by  $T$ , where  $B$  is the carrier set of the algebra  $\mathcal{B} = \langle B, G \rangle$  defined in Lemma 2. Then the triple  $\xi = [\alpha_1, \alpha_2; \chi]$  determines a homotopy of  $L$  into  $\mathcal{B} = \langle B, G \rangle$ .

Proof. As  $\chi$  is defined only on the family  $\mathcal{M}_{\mathcal{T}}$ , we have to define  $\chi$  on  $L$  such that it gives the desired homotopy property. For the two operations of  $L$  we define:

$\chi(f(a_1, a_2)) = \chi(M_0)$  which is obtained from  $\varphi f(\chi(M_1), \chi(M_2))$ , where  $a_1 \in M_1^{\wedge}$  and  $a_2 \in M_2^{\vee}$  (see Lemma 2 (ii)). As  $a = a \vee a = a \wedge a$  in  $L$ , we obtain  $\chi(a) = \chi(f(a, a))$  which is already defined. By using this definition for  $\chi: L \rightarrow B$  it obviously holds that  $\chi(f(a_1, a_2)) = \varphi f(\alpha_1(a_1), \alpha_2(a_2))$  for any  $a_1, a_2 \in L$ , where  $\varphi f$  can be substituted by  $f$  as  $L$  and  $\mathcal{B}$  are of the same type. This completes the proof.
